3B. Hydrates and Their Thermal Decompositions

Introduction

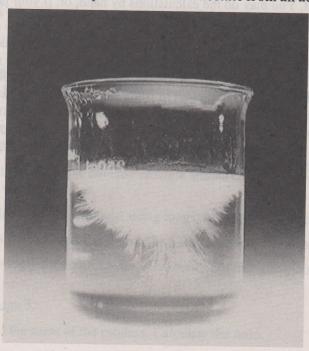

What is a *hydrate*? A hydrate is a salt that has crystallized from aqueous solution with weakly bound water molecules *contained* in the crystals (Ebbing/Gammon, Section 2.8).

Consider the crystallization of sodium acetate ($NaC_2H_3O_2$) as an example. This process is shown in Figure 3B.1. The crystals that you see in the photograph can be removed from the solution by filtration. If these crystals are then allowed to sit in the open air for a few hours, all of the residual moisture on their surfaces will evaporate. They will appear to be dry. Nevertheless, water will still be present, and it will be present in a definite stoichiometric amount. Chemical analysis would reveal that 3 water molecules accompany every formula unit of sodium acetate. This is shown by writing the formula as $NaC_2H_3O_2 \cdot 3H_2O$.

The definite stoichiometry occurs because the water in a hydrate occupies definite sites in the crystalline lattice, just as Na⁺ and Cl⁻ ions occupy definite positions in the NaCl lattice. Because this water occupies definite sites, it must be present in definite stoichiometric amounts. The quantity of water will not change as long as the temperature (and pressure) is not altered significantly. A substantial increase in temperature, however, will cause the loss of hydrate water.

The crystallization of the trihydrate of sodium acetate from an aqueous solution.

68 Experiment 3B

Purpose

You will use mass relationships to identify the product that you obtain from the thermal decomposition of barium chloride dihydrate (BaCl₂ • 2H₂O). You will also have the opportunity to observe the thermal decomposition of several other hydrates.

Concept of the Experiment

In the first part of this experiment, you will examine the quantitative aspects of the thermal decomposition of BaCl₂ • 2H₂O. When this substance is heated, there are at least three possible reactions:

$$BaCl_{2} \cdot 2H_{2}O(s) \xrightarrow{\Delta} BaCl_{2} \cdot H_{2}O(s) + H_{2}O(g)$$

$$BaCl_{2} \cdot 2H_{2}O(s) \xrightarrow{\Delta} BaCl_{2}(s) + 2H_{2}O(g)$$

$$BaCl_{2} \cdot 2H_{2}O(s) \xrightarrow{\Delta} BaO(s) + H_{2}O(g) + 2HCl(g)$$

The product of the first reaction is the monohydrate, BaCl₂ • H₂O. Alternatively, all of the water may be lost so that anhydrous (water-free) BaCl₂ is obtained, as shown in the second equation. Finally, the decomposition may take the course shown in the third equation. A simple loss of water has not occurred. HCl is also liberated, so the oxide, BaO, remains when the reaction is complete.

How will you know which reaction has occurred? Because you will know the mass of the reactant, you will be able to calculate the mass of each possible product. You will then be able to identify the product by comparing the measured mass of the product with the masses that you have calculated. This reaction is particularly "well behaved," so your identification will be unambiguous if you have followed the directions carefully. Moreover, you will pool your results with those of your classmates to establish the precision of the experiment. You may do the calculations by hand, or, if your laboratory instructor wishes, you can use a computer and the Internet (Appendix A).

You will also have the opportunity to observe the colorful thermal decompositions of CrCl₃ • 6H₂O, CoCl₂ • 6H₂O, NiSO₄ • 7H₂O, and CuSO₄ • 5H₂O. Because these reactions are not as well behaved as the one involving BaCl₂ • 2H₂O, you will study only their qualitative aspects. Remember that a reaction must accompany every color change. Simple loss of water may occur on gentle heating, but more extensive decomposition could occur with protracted, strong heating. For example, CuSO₄ • 5H₂O will lose water to give anhydrous CuSO₄, which, in turn, can lose gaseous SO₃ to give CuO. Moistened blue litmus paper would detect this reaction, however, because SO₃ reacts with water to give sulfuric acid (H₂SO₄), and acids cause blue litmus paper to turn pink.

Procedure

Getting Started

- 1. Obtain a crucible and lid. Wash, rinse, and dry them. Also obtain 4 small test tubes and 8 small strips of blue litmus paper.
- 2. Place the covered crucible in a clay triangle on an iron ring that is attached to a ring stand. Adjust the height of the ring so that the bottom of the crucible will be in the hottest part of the flame of your laboratory burner. Figure 3A.1 from Experiment 3A shows the correct arrangement.
- 3. Obtain directions for discarding the solid products that will be produced in this experiment.

Doing the Quantitative Experiment

- 1. Heat the covered crucible strongly for about 3 min. The bottom of the crucible should attain a redhot glow during this time.
- 2. Move the burner and allow the crucible to cool (5–10 min). When the crucible is cool, you should feel no heat when you place one of your fingers about 1/2 inch from the bottom of the crucible.

CAUTION: Avoid burning your fingers. Do not touch the crucible or the iron ring at any time during this experiment.

- 3. When the covered crucible is cool, transfer it to the pan of your most precise balance, using crucible tongs and holding a wire gauze under it. If you must wait to use the balance, do not place the crucible directly on the bench. Put it on the wire gauze or leave it in the clay triangle.
- 4. Obtain and record the mass of the covered crucible.
- 5. Repeat Steps 1 and 4 until two consecutive masses differ by not more than ±0.001 g (or any other range stipulated by your laboratory instructor). Use the last mass that you obtain in subsequent calculations.
- 6. Using a platform balance, a triple beam balance, or an electronic top-loading balance, add about 1.4–1.5 g of BaCl₂ 2H₂O to a piece of waxed weighing paper whose mass you have already determined.
- 7. Uncover the crucible using crucible tongs, add the sample of BaCl₂ 2H₂O to the crucible, dispose of the weighing paper, and cover the crucible again.
- 8. Obtain and record the mass of the covered crucible and its contents. Calculate and record the mass of BaCl₂ 2H₂O in the sample.
- 9. Transfer the crucible to the clay triangle, using tongs. Leave the lid slightly ajar.
- 10. Heat the crucible slowly by brushing it with the flame for about 2–3 min.
- 11. Heat the crucible strongly for about 15 min. The bottom of the crucible should be red hot during this time.
- 12. Repeat Steps 2 through 5.
- 13. Calculate and record the mass of the product. Calculate the ratio

Mass of product/mass of BaCl₂ • 2H₂O

Share your value with your classmates and obtain their values for this ratio.

Doing the Qualitative Experiment

- 1. Place a pea-sized portion of CrCl₃ 6H₂O in one of the test tubes.
- 2. With a test tube clamp, hold the test tube at an angle of about 45°, and quickly move the test tube in and out of the hottest part of the flame from your burner.
- 3. Note and record all color changes. Immediately test with blue litmus paper the water that condenses on the upper surface of the test tube.
- 4. When no further color changes are apparent, hold the test tube directly in the hottest part of the flame for about 1 min. Repeat the test with moistened blue litmus paper. Record your observations.
- 5. Repeat Steps 1 through 4 with, in turn, pea-sized portions of CoCl₂ 6H₂O, NiSO₄ 7H₂O, and CuSO₄ 5H₂O.

CAUTION: Before you leave the laboratory, make sure that your gas outlet and those of your neighbors are closed.

Hydrates and Their Thermal Decompositions

Prelaboratory Assignment

- 1. Provide definitions for the following words:
 - a. Hydrate

- b. Anhydrous
- 2. What are the differences between water on the surface of the crystals of a hydrate and hydrate water itself?

3. a. The thermal decomposition of 1.6608 g of MgSO₄ • H₂O produces 1.4446 g of a product in a well-behaved reaction. There are two possibilities:

$$MgSO_4 \bullet H_2O(s) \xrightarrow{\Delta} MgSO_4(s) + H_2O(g)$$

$$MgSO_4 \bullet H_2O(s) \xrightarrow{\Delta} MgO(s) + SO_3(g) + H_2O(g)$$

Complete the following table, and then identify the correct solid product by comparing the calculated masses of MgSO4 and MgO with the observed mass of the product.

Substance	Formula Weight	Moles	Mass (g)
MgSO ₄ • H ₂ O	you leave the labor te of your accellurs	itory, author stri	1.6608
MgSO ₄			
MgO			Anhydrous

Because the observed mass of the product is 1.4446 g, the product is _____

- b. What qualitative test could be used to substantiate this result?
- 4. What special safety precautions have been cited in this experiment?
